See also: How to Plan an Effective Photo Shoot One of the few things that Photoshop doesn't do well is sharpening. This isn't always a problem; some images are just naturally soft. However, when you need a really sharp image, don't attempt to use this "canned" feature, as there are better, faster, and more effective ways to sharpen images. Sharpening tools can actually make images look worse. Since Photoshop is a raster image editor, it can be looked at as a collection of dots, or pixels. The image contains high and low, white and black tones, and a copy of the pixels in neighboring pixels. When you sharpen the image, you're only copying each white and black pixel to a corresponding high and low pixel in the output. This creates a high-frequency noise that throws the edges of the image off. If you're not careful, you might even end up removing too much detail from the image. Doing a good job of sharpening requires a good understanding of the image's detail. The fewer pixels in the image, the smaller each dot becomes. There are three separate ways to sharpen: sharpening the image pixel by pixel, sharpening the image as a whole (that is, sharpening a larger image area), and sharpening a smaller area. 1. Pixel-by-Pixel Sharpening Traditionally, you sharpen an image by outlining each individual pixel. This is the most common way to sharpen a photo. The image is displayed in the upper left corner of your Photoshop program's workspace. Left: The original image. Right: The sharpened image. Click the image to see the sharpening settings. The sharpening process is similar to a circular saw. You start by placing one edge of the sharpening tool over an area of pixels to be sharpened. When you release the mouse button, the sharpening tool moves to the next pixel. You repeat this process, slowly "cutting" your way through the image, until you're finished. The default sharpening settings do a good job at most times. However, if you're working with a high-resolution image, or you want maximum sharpening, you will want to get the settings right. Here are a few things to keep in mind when sharpening: ■ The more pixels you move with the edges of the sharpening tool, the more accurate the result will be

Q: Question about Symmetry property of a function Let $f: \mathbb{R} \rightarrow \mathbb{R}$ and suppose that f is symmetric about the origin. Prove that $f(t)=f(-t)$. Proof: If f is symmetric about the origin then $f(t)=f(-t)$. (Symmetry property) Since f is continuous, $\lim_{t \rightarrow -\infty} f(t)=f(0)$ and $\lim_{t \rightarrow +\infty} f(t)=f(0)$. So $f(-0)=f(0)$. (A theorem: If f is continuous at the origin, then $f(0)=0$) Is it proof? Could you provide a detailed proof? A: You don't need continuity; a necessary and sufficient condition is that $f(x+y)=f(x)+f(y)$ for all x,y . Or if you prefer: Let $M=\max\{|f(x)|:x \in \mathbb{R}\}$. Suppose there were $x,y \in \mathbb{R}$ with $|f(x+y)|$

Clonidine suppresses the dehiscence of wet and dry berkeley clamp wounds. Clonidine (1 microgram/kg) suppressed the increase in wet weight and collagen content of skin wounds (0.5 cm²) closed with the Berkeley wet/dry clamp. Skin wounds closed with the clamp were associated with a marked increase in stress proteins, induced by the stress of being cut to the amount required for initiating healing, thereby causing an increase in collagen content and a delay in epithelialisation. However, exposure of wounds to clonidine suppressed both the increase in wet weight and collagen content of the skin wounds. Clonidine (4 micrograms/kg) suppressed the increase in stress proteins also, and in addition caused a reduction in collagen content. Wound closure was initiated earlier than in the controls, as shown by a shorter epithelialisation period. Clonidine (1 microgram/kg) was not associated with any gross changes in blood flow or perfusion. Clonidine (4 micrograms/kg) suppressed the increase in blood flow and perfusion seen after skin wounding. Transformation of tyrosine-phosphorylated phosphoproteins in *Saccharomyces cerevisiae*. A method was developed in which the tyrosine phosphorylation status of cellular proteins could be monitored by Western blotting with phosphotyrosine antibodies. The technique was employed to detect the tyrosine-phosphorylated (hereinafter referred to as Tyr-P) proteins in yeast cells transformed with the ERE1 or the 2xEJLA expression vectors. The expression of both the ERE1 and the 2xEJLA plasmids resulted in an overall increase in the Tyr-P proteins in the transformed cells. The size distribution of the Tyr-P proteins was similar in the two transformed cell lines. Although the majority of the Tyr-P proteins (62.3%) were of apparent molecular mass (Mr) 90 kDa, Tyr-P proteins of 62, 44, 32, 26, 14 and 11 kDa were also observed. In addition, a new Tyr-P species of apparent Mr 60 kDa was observed. The analysis of the tyrosine-phosphorylation status of the ERE1-transformed cells at different stages of growth indicated that two of the low Mr Tyr-P proteins observed in exponentially growing cells were of higher Mr (86 and 90 kDa) during the decline phase of the growth cycle
